

Plague WARNING: Major cities face BLOODTHIRSTY disease-riddled super rats

POLLUTED cities are causing rats to evolve into more vicious and stronger creatures, according to a shocking new report.

By Christine Younan / Published 7th November 2017

The research claims major cities around the globe are now riddled with super-sized disease rodents, which have been forced to mutate.

Humans are causing disgusting critters lower down the pecking order to make these rats grow at a faster rate.

Marc Johnson, an associate professor of biology at the University of Toronto, said: “As we build cities, we have little understanding of how they are influencing organisms that live there.”

The study – which was mainly focused on London – also found that bedbugs which were scarce two decades ago in the capital are now immune to insecticides.

“It’s good news that some organisms are able to adapt, such as native species that have important ecological functions in the environment,” said Marc.

“But it can also be bad news that the ability of some of these organisms to adapt to our cities might increase the transmission of the disease.”

Jason Munshi-South, who is an associate professor of biological sciences at Fordham University and co-author of the study, added: “Traditionally, we’ve thought about evolution as a long-term process driven by environmental pressures and the interactions between species.

“But now there is a new driver that is rapidly changing many other species, which is how they interact with humans and our built environment.

“Humans and our cities are one of the most dominant forces of contemporary evolution now.”

It comes after health experts warned a killer virus, similar to Ebola, has broken out and it’s untreatable.

And “something different” about a new Black Death outbreak is feared to spread across the world.

The deadly disease has spread into more African countries after taking root in Madagascar.
